

Assignment 2

Name: Tanvi Ohri, Roll No.: 170123051

Internet Connection used: USB tethering through Airtel, Vodafone Mobile networks. In case of common observations, screenshots are attached for Airtel network.

Q1.

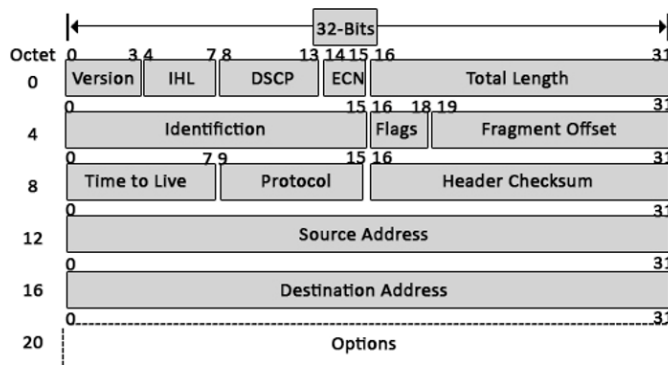

1. Link Layer: Ethernet II

The Destination Address specifies to which adapter the data frame is being sent. The Source Address specifies from which adapter the message originated. The Ethertype specifies the memory buffer in which to place this frame. Following the Ethertype are 46 to 1500 bytes of data, generally consisting of upper layer headers such as TCP/IP or IPX and then the actual user data. CRC checksum is meant for error detection.

2. Network Layer: Internet Protocol v4 for Airtel and Internet Protocol v6 for Vodafone

An IP packet consists of a header section and a data section. Data section holds the payload given to it by the Transport Layer. Headers are explained below:

Ipv4: Version: equal to 4, Internet Header Length (IHL) has 4 bits which is the number of 32-bit words in header, Differentiated Services Code Point (DSCP) used in QoS, Explicit Congestion Notification (ECN) allows end-to-end notification of network congestion without dropping packets, Total Length is 16-bit field which defines the entire packet size in bytes, identification field is primarily used for uniquely identifying the group of fragments of a single IP datagram, flags bit is used to control or identify fragments (0 th bit: Reserved and is always 0; 1 st bit: Don't Fragment (DF); 2 nd bit: More Fragments (MF)), Fragment Offset specifies the offset of a particular fragment,

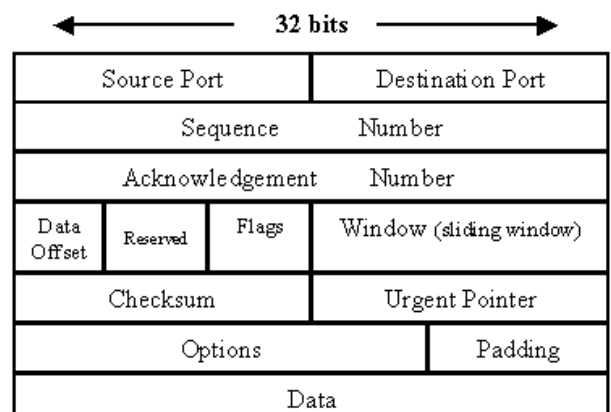

Time To Live (TTL) helps prevent datagrams from persisting on network forever, Protocol defines the protocol used in the data portion of the IP datagram, Header Checksum is used for error-checking of the header, Source address & Destination address is the Ipv4 address of the sender and receiver of the packet respectively

Ipv6: Version: IP version 6, Traffic Class: used in congestion control, Flow Label: QoS management, Payload length: payload length in bytes, Next header: specifies the next encapsulated protocol, Hop Limit: replaces the ttl field of Ipv4, Source and Destination addresses: 128 bits each

3. Transport Layer: Transmission Control Protocol

TCP segment consists of data bytes to be sent and a header, which can range from 20-60 bytes. The header fields are: Source and destination TCP ports which are the communication endpoints for sending and receiving devices, sequence and acknowledgement numbers to mark the ordering in a group of messages, data offset stores the total size of a TCP header in multiples of four bytes, Reserved data in TCP headers always has a value of zero, a set of six standard and three extended control flags (each an individual bit representing on or off) to manage data flow in specific situations, window size to regulate how much data sender sends to a receiver before requiring an

acknowledgment in return, checksum for error detection, urgent pointer can be used as a data offset to mark a subset of a message which require priority processing. Optional TCP data can be used to include support for special acknowledgment and window scaling algorithms.

4. Application Layer: Secure Sockets Layer and Hypertext Transfer Protocol

Handshake Protocol	Change cipher spec protocol	Alert protocol	HTTP
SSL Record Protocol			
TCP			
IP			

SSL: It can be used with any protocol that uses TCP as the transport layer. The basic unit of data in SSL is a record. Each record consists of a five-byte record header, followed by data. The header contains – Record Type: four types- Handshake, Change Cipher Spec, Alert, Application Data, Record Version is 16-byte value formatted in network order, Record Length is 16-byte value.

HTTP: Hypertext Transfer Protocol (HTTP) header fields provide required information about the request or response, or about the object sent in the message body. There are four types of HTTP message headers: General-header have applicability for both request and response applicability only for request messages, Server Response-header have applicability only for response messages, Entity-header defines meta information about the entity-body. The header fields are - Connection general-header allows the sender to specify options that are desired for that particular connection and must not be communicated by proxies over further connections, Date, Authorization request-header field value consists of credentials containing the authentication information of the user agent, Cookie request-header field value contains a name/value pair request-header contains an Internet e-mail address for the human user who controls the requesting user agent, Host request-header is used to specify the Internet host and the port number of the resource being requested, Proxy-Authorization request-header allows the client to identify itself to a proxy which requires authentication, User-Agent request-header contains information about the user agent, Location response-header is used to redirect the recipient to a location other than the Request-URI for completion, Server response-header contains information about the software used by the origin server to handle the request.

The general format is similar to the format used for e-mail messages: headers, an empty line and then a message body. All text lines are terminated with the standard “CRLF” control character sequence; the empty line contains just those two characters and nothing else. The headers are always sent as regular text; the body, however, may be either text or 8-bit binary information, depending on the nature of the data to be sent. The start line is a special text line that conveys the nature of the message. In a request, this line indicates the nature of the request, in the form of a method, as well as specifying a URI to indicate the resource that is the object of the request. Responses use the start line to indicate status information in reply to a request.

HTTP request message: general format

Q2.

1. Link Layer: Ethernet II

Destination contains MAC Address of the destination endpoint. Source contains the MAC address of the sending device, which is my PC. Both addresses are unicast and locally administered. Type indicates which protocol is encapsulated in the payload of the frame.

```

▼ Ethernet II, Src: _gateway (f2:f8:38:11:37:9c), Dst: tanvi-HP-Notebook-e1cb (de:b0:49:3c:e1:cb)
  ▼ Destination: tanvi-HP-Notebook-e1cb (de:b0:49:3c:e1:cb)
    Address: tanvi-HP-Notebook-e1cb (de:b0:49:3c:e1:cb)
    .... 1. .... = LG bit: Locally administered address (this is NOT the factory default)
    .... 0 .... = IG bit: Individual address (unicast)
  ▼ Source: _gateway (f2:f8:38:11:37:9c)
    Address: _gateway (f2:f8:38:11:37:9c)
    .... 1. .... = LG bit: Locally administered address (this is NOT the factory default)
    .... 0 .... = IG bit: Individual address (unicast)
  Type: IPv4 (0x0800)
  
```

2. Network Layer: Internet Protocol v4

```

Internet Protocol Version 4, Src: video-edge-c683c4.sin01.abs.hls.ttvnw.net (45.113.129.101), Dst: tanvi-HP-Notebook-e1cb (192.168.42.72)
  0100 .... = Version: 4
  .... 0101 = Header Length: 20 bytes (5)
  ► Differentiated Services Field: 0x00 (DSCP: CS0, ECN: Not-ECT)
    Total Length: 1440
    Identification: 0xe33c (58172)
  ► Flags: 0x4000, Don't fragment
    Time to live: 55
    Protocol: TCP (6)
    Header checksum: 0xc154 [validation disabled]
    [Header checksum status: Unverified]
    Source: video-edge-c683c4.sin01.abs.hls.ttvnw.net (45.113.129.101)
    Destination: tanvi-HP-Notebook-e1cb (192.168.42.72)
  
```

Version is 4 as Ipv4 is being used. Header length is 20 bytes and as it counts in 4 bytes, its value is 5. DCP: CS0 implies best-effort delivery service and ECN: Not-ECT implies Non ECN-Capable Transport. Total Length of the packet is 1440 bytes. Flag is set to “Don’t Fragment” which is an instruction not to break this packet into smaller

fragment. TTL is 55 hops. Protocol used at the layer above is TCP. Header Checksum is used for error detection of the packet header. Source and Destination contains the IP address of the website and my PC respectively.

3. Transport Layer: Transmission Control Protocol

```
Transmission Control Protocol, Src Port: 443, Dst Port: 40256, Seq: 6863209, Ack: 44922, Len: 1388
Source Port: 443
Destination Port: 40256
[Stream index: 0]
[TCP Segment Len: 1388]
Sequence number: 6863209 (relative sequence number)
[Next sequence number: 6864597 (relative sequence number)]
Acknowledgment number: 44922 (relative ack number)
1000 .... = Header Length: 32 bytes (8)
Flags: 0x010 (ACK)
Window size value: 363
[Calculated window size: 363]
[Window size scaling factor: -1 (unknown)]
Checksum: 0x4891 [unverified]
[Checksum Status: Unverified]
Urgent pointer: 0
Options: (12 bytes), No-Operation (NOP), No-Operation (NOP), Timestamps
[SEQ/ACK analysis]
[Timestamps]
TCP payload (1388 bytes)
TCP segment data (1220 bytes)
TCP segment data (116 bytes)
```

The Source and Destination Ports are the port numbers on source and destination among which the communication is happening. Header Length is 32 bytes, so value 8 is stored (as counting happens in 4 bytes). Flags ACK is set which means that the machine sending the packet with ACK is acknowledging data that it had received from the other machine. The Window Size Value indicate how much buffer space is available on source for receiving packets. Checksum is used for error detection in the entire packet. Scaling Factor is the number by which the window size displayed is to be scaled.

4. Application Layer: Secure Sockets Layer

```
Secure Sockets Layer
  TLSv1.2 Record Layer: Application Data Protocol: http-over-tls
    Content Type: Application Data (23)
    Version: TLS 1.2 (0x0303)
    Length: 8041
    Encrypted Application Data: f724c2ecf35918fe4ba44b69da325d13eafa03eae550a7d8..
Secure Sockets Layer
  TLSv1.2 Record Layer: Application Data Protocol: http-over-tls
    Content Type: Application Data (23)
    Version: TLS 1.2 (0x0303)
    Length: 19
    Encrypted Application Data: 6508eb543afddf7a022e97c5fb7e63e7e05a34
  TLSv1.2 Record Layer: Application Data Protocol: http-over-tls
    Content Type: Application Data (23)
    Version: TLS 1.2 (0x0303)
    Length: 23
    Encrypted Application Data: 24b20e2b1d0b80f2220e1295f0c58cd4edbea98c535763
```

The Application-Data-Protocol indicates the protocol used at the application layer, which is http (secured with tls) here. Content Type indicates the type of payload, which is the Application Data here. Version tells the protocol version used for securing the communication, which is TLS 1.2 here. Length is the length of the message. Encrypted Application Data is unreadable by anyone who does not have the required key.

5. Application Layer: Hypertext Transfer Protocol

```
Secure Sockets Layer
Hypertext Transfer Protocol
  [truncated]GET /v1/segment/CvwDtT6F7eVHBe76SBAo1HETjpEjqvR_NbrmGZycNcuSnNKfB7RLPd8IBvK9ntjC0zIAJYrSm05TzU_c1tt0VEx8RsJytGCCi_qtUjESB7_Gr2mCr5QDh0g4RRrV6dEDgbdzgQDwo74yp0
Host: video-edge-c55900.sin01.abs.hls.ttvnw.net\r\n
Connection: keep-alive\r\n
User-Agent: Mozilla/5.0 (X11; Linux x86_64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/79.0.3945.130 Safari/537.36\r\n
Accept: */*\r\n
Origin: https://www.twitch.tv\r\n
Sec-Fetch-Site: cross-site\r\n
Sec-Fetch-Mode: cors\r\n
Accept-Encoding: gzip, deflate, br\r\n
Accept-Language: en-GB,en-US;q=0.9,en;q=0.8\r\n
\r\n
```

GET request method is being used to retrieve the stream from the server. Host specifies the address where the resource is located. Connection: keep-alive tells the server to maintain the connection. User-Agent indicates the software program that is acting on behalf of the user.

Q3.

Data Privacy and Integrity is of utmost concern in today's day and age. An SSL(Secure Sockets Layer) certificate is a bit of code on your web server that provides security for online communications. When a web browser contacts your secured website, the SSL certificate enables an encrypted connection. TLS (Transport Layer Security) is used to encrypt the data between the communication endpoints. Hence, these two provide data privacy and data integrity.

UDP is faster, which is a desirable quality for a live streaming website. However, TCP is more reliable and compatible with HTTP than UDP. Hence, Twitch uses TCP at Transport Layer. Less speed is compensated because of increased bandwidths during distribution (from CDN (Content Delivery Network) where the data is first sent).

At network layer, IP (Internet Protocol) is used because TCP is only compatible with it. TCP ensures reliable delivery and correct order of data.

Ethernet II is used at link layer as it ensures reliable data transfer, proper error handling (CRC), synchronization (preamble) and flow control.

Internet Control Message Protocol version 6 (ICMPv6) is a supporting protocol and used by networks devices for sending the error messages and operations information. Since IP does not have a inbuilt mechanism for sending error and control messages, it depends on Internet Control Message Protocol(ICMP) to provide an error control. It is used for reporting errors and management queries.

Streaming and Pausing Functionalities: On playing a video on the application, the server begins to send Application Data to the PC (HTTP encrypted by TLS used), these packets are acknowledged by a packet from my PC (TCP protocol is used). Sometimes, acknowledgment packets may carry data, called piggy-backing (identified by non-zero length). While the video is paused, KEEP-ALIVE messages are periodically exchanged to keep the connection alive (TCP protocol is used for this).

Q4.

Streaming and Pausing Functionalities: On playing a video on the application, the server begins to send Application Data to the PC, these packets are acknowledged by a packet from my PC. Sometimes, acknowledgment packets may carry data, called piggy-backing (identified by non-zero length).

37	0.000069918	video-weaver.sin01...	tanvi-HP-Notebook-d...	TCP	1454	443 → 60584 [ACK] Seq=8658 Ack=1231 Win=93 Len=1388 TSval=3431548666 TSecr=2479319354 [TCP ...

Streaming and pausing lead to communication between different ports (eg. 60584 and 47928 respectively, at 5pm) on my PC and the same port 443 on the twitch server.

While the video is paused, KEEP-ALIVE messages are periodically exchanged to keep the connection alive.

Time	Source	Destination	Protocol	Length	Info

Handshaking Sequences:

-> **DNS querying:** First, when the site is loaded, DNS querying is done by the browser. A series of messages are exchanged, so that the browser may learn the IP address of the website.

-> **TCP Handshaking:** A 'three-way handshake' between the source (my PC) and the destination (the website server). Port 44538 on my computer and port 443 on the destination system are being used. First, a SYN packet is sent from my PC to the server to establish connection and to synchronize the sequence number. The server replies with a SYN-ACK, acknowledging that it has received the initial packet, and in the same packet, it tell the source to synchronize with its sequence number.

Time	Source	Destination	Protocol	Length	Info
33	5.618712379	tanvi-HP-Notebook-e...	video-weaver.sin01...	TCP	74 44538 → 443 [SYN] Seq=0 Win=29200 Len=0 MSS=1460 SACK_PERM=1 TSval=2789644768 TSecr=0 WS=128
34	5.784772464	video-weaver.sin01...	tanvi-HP-Notebook-e...	TCP	74 443 → 44538 [SYN, ACK] Seq=0 Ack=1 Win=28960 Len=0 MSS=1400 SACK_PERM=1 TSval=3114718282 TSecr=2789644768
35	5.784842225	tanvi-HP-Notebook-e...	video-weaver.sin01...	TCP	66 44538 → 443 [ACK] Seq=1 Ack=1 Win=29312 Len=0 TSval=2789644934 TSecr=3114718282

-> TLS Handshaking: To make the connection secure, TLSv1.2 is being used. The first message in the TLS Handshake is the Client Hello which is sent by the client to initiate a session with the server. The server responds with Server Hello. The change cipher spec message, transmitted by both the client and the server, defines the re-negotiated cipher spec and keys that will be used for all the messages exchanged henceforth.

No.	Time	Source	Destination	Protocol	Length	Info
36	5.788832729	tanvi-HP-Notebook-e...	video-weaver.sin01...	TLSv1.2	645	Client Hello
37	5.887942555	tanvi-HP-Notebook-e...	client-event-report...	TCP	66	58642 → 443 [ACK] Seq=1 Ack=1 Win=369 Len=0 TSval=2295617130 TSecr=3763152797
38	5.927124943	video-weaver.sin01...	tanvi-HP-Notebook-e...	TLSv1.2	203	Server Hello, Change Cipher Spec, Encrypted Handshake Message
39	5.927174924	tanvi-HP-Notebook-e...	video-weaver.sin01...	TCP	66	44538 → 443 [ACK] Seq=580 Ack=138 Win=30336 Len=0 TSval=2789645077 TSecr=3114718428
40	5.927854029	tanvi-HP-Notebook-e...	video-weaver.sin01...	TLSv1.2	117	Change Cipher Spec, Encrypted Handshake Message
41	5.930577379	tanvi-HP-Notebook-e...	video-weaver.sin01...	TLSv1.2	1296	Application Data

-> Connection Termination: When the communication is over, there is an exchange of messages to terminate the TCP connection. My PC first sends a FIN-ACK message. The server acknowledges it and sends its own FIN-ACK message, which is acknowledged by my PC. This is a four-way handshake to end the connection.

Q6.

The IP addresses of the source server are different at different times. This maybe because of different network traffic at different times. Hence, some load balancing takes place, where some requests are redirected to a different server, thus reducing network congestion.

Time	IP Address
8 am	185.42.207.190
6 pm	185.42.207.125
12 am	45.113.129.78
